# Live Video Streaming Systems

- On-demand or **live** streaming
- Client-Server or **Peer-to-Peer (P2P)**
  - **SopCast**, PPLive, PPStream, ...
- 83 million users in 2013 (predicted)
  - Sentinelli et. al. - Will IPTV Ride The Peer-to-Peer Stream? - 2007

HOW DOES THE STRUCTURE OF  
THE OVERLAY NETWORK EVOLVE  
OVER TIME DURING A LIVE  
TRANSMISSION?

# Goals

- Characterize the temporal evolution of the P2P overlay network over a transmission
  - Local View: individual nodes
  - Global View: whole network
- Build knowledge to:
  - Create more realistic P2P synthetic workloads
  - Drive future protocol designs and evaluations

# Previous Characterizations of P2P Live Systems

- Structural properties
  - Static view of the network
  - Few crawlers ( $\leq 70$ )
    - Possibly less representative view of the network
- Temporal evolution
  - Focused on peer degree only

# DATA COLLECTION METHODOLOGY

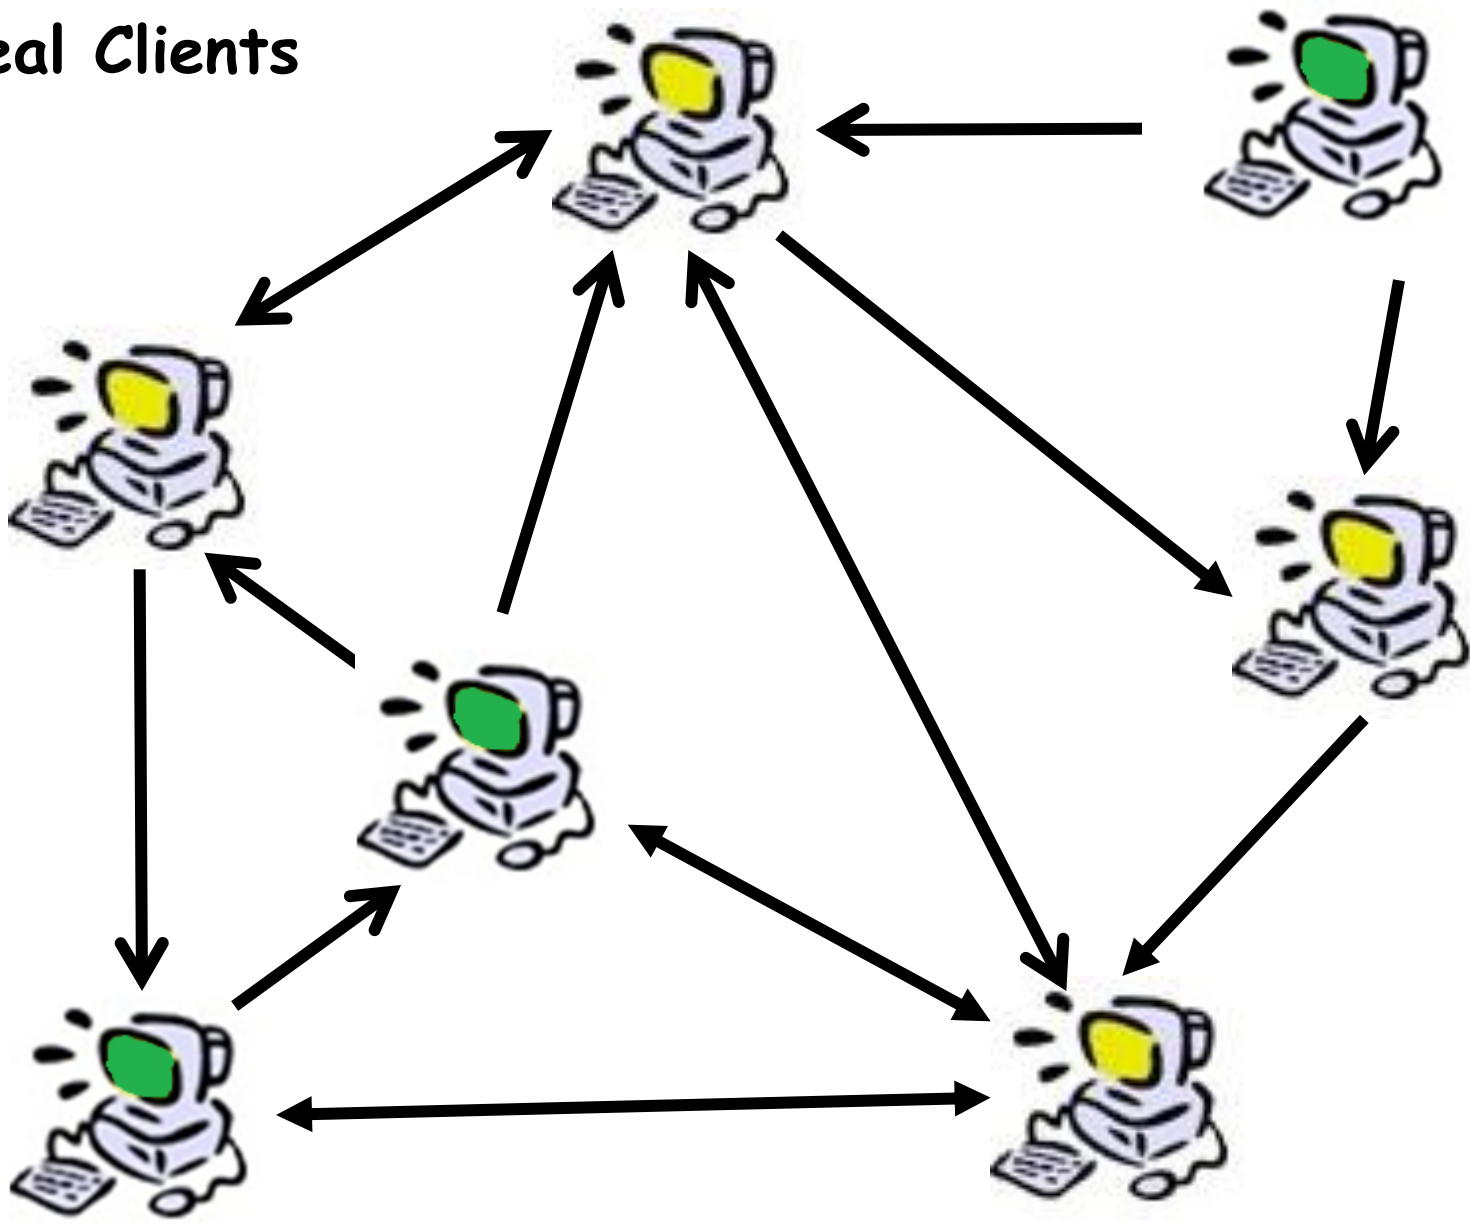

# Data Crawling Setup

- SopCast Clients running on PlanetLab nodes
  - CCTV-1 channel
  - 8pm (China local time)
- Wireshark - UDP/TCP port
- Time synchronization (NTP)
- Unconstrained peer bandwidth (upload and download)

 Crawlers on PlanetLab

 Real Clients

 Crawlers on PlanetLab

 Real Clients

# Data Crawling

- Crawlers remain connected throughout transmission
- For each packet received/sent by each crawler:
  - Date and time of the transmission
  - Source IP Address
  - Destination IP Address
  - Packet size
- Merge data collected by all crawlers
- Snapshots of the network every 60 seconds

# Overview

Number of experiments	7
Period of experiments	10/28/10 to 11/17/10
Number of crawlers	200 until 465
Channel	CCTV-1
Local time	8 pm
Transmission duration	40 minutes
Duration of each snapshot	60 seconds

# CHARACTERIZATION

# Main Steps

- Properties of individual nodes
  - Centrality profiles
  - Changes in the profile of a node over time
  - Changes in the list of partners over time
- Properties of network as a whole

# Main Steps

- Properties of individual nodes
  - Centrality profiles
    - Changes in the profile of a node over time
    - Changes in the list of partners over time
- Properties of network as a whole

# Centrality Profiles

What is the importance of a node in terms of its centrality in the network?

- Centrality Metrics:
  - Degree: number of partnerships
  - Betweenness:
    - Probability of a node to be in a shortest path between two other nodes
  - Closeness:
    - Average distance between a node and all other nodes in a network (reachable from it)

# Centrality Profiles

- During each transmission, each node is represented by 3 features:
  - Average degree
  - Average betweenness
  - Average closeness
- k-means clustering algorithm
- Identification of three profiles (in all experiments)
  - High Centrality (HC)
  - Intermediate Centrality (IC)
  - Low Centrality (LC)

# Degree Distribution

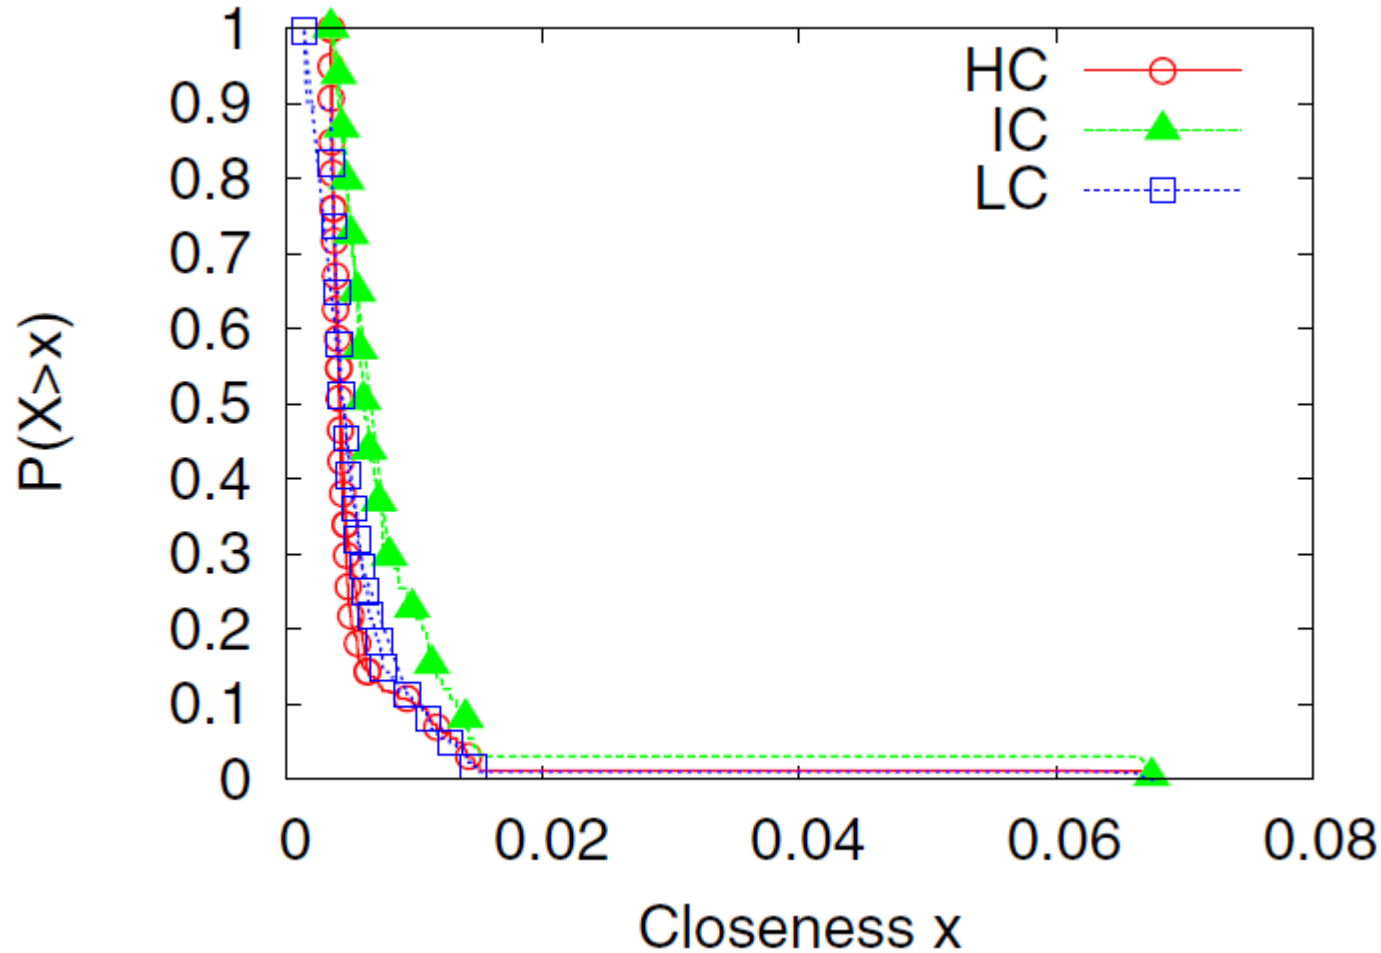

Nodes with HC profile have much more partnerships

# Betweenness Distribution

Nodes with HC profile are located in the path of many more nodes than the other profiles

# Closeness Distribution

Closeness is not able to clearly distinguish the profiles

# Main Steps

- Properties of individual nodes
  - ✓ Centrality profiles
  - Changes in the profile of a node over time
    - Changes in the list of partners over time
- Properties of network as a whole

# How does the profile of a node change over time?

- HC
- IC
- LC

# How does the profile of a node change over time?

- HC
- IC
- LC

# How does the profile of a node change over time?

- HC
- IC
- LC

# How does the profile of a node change over time?

- HC
- IC
- LC

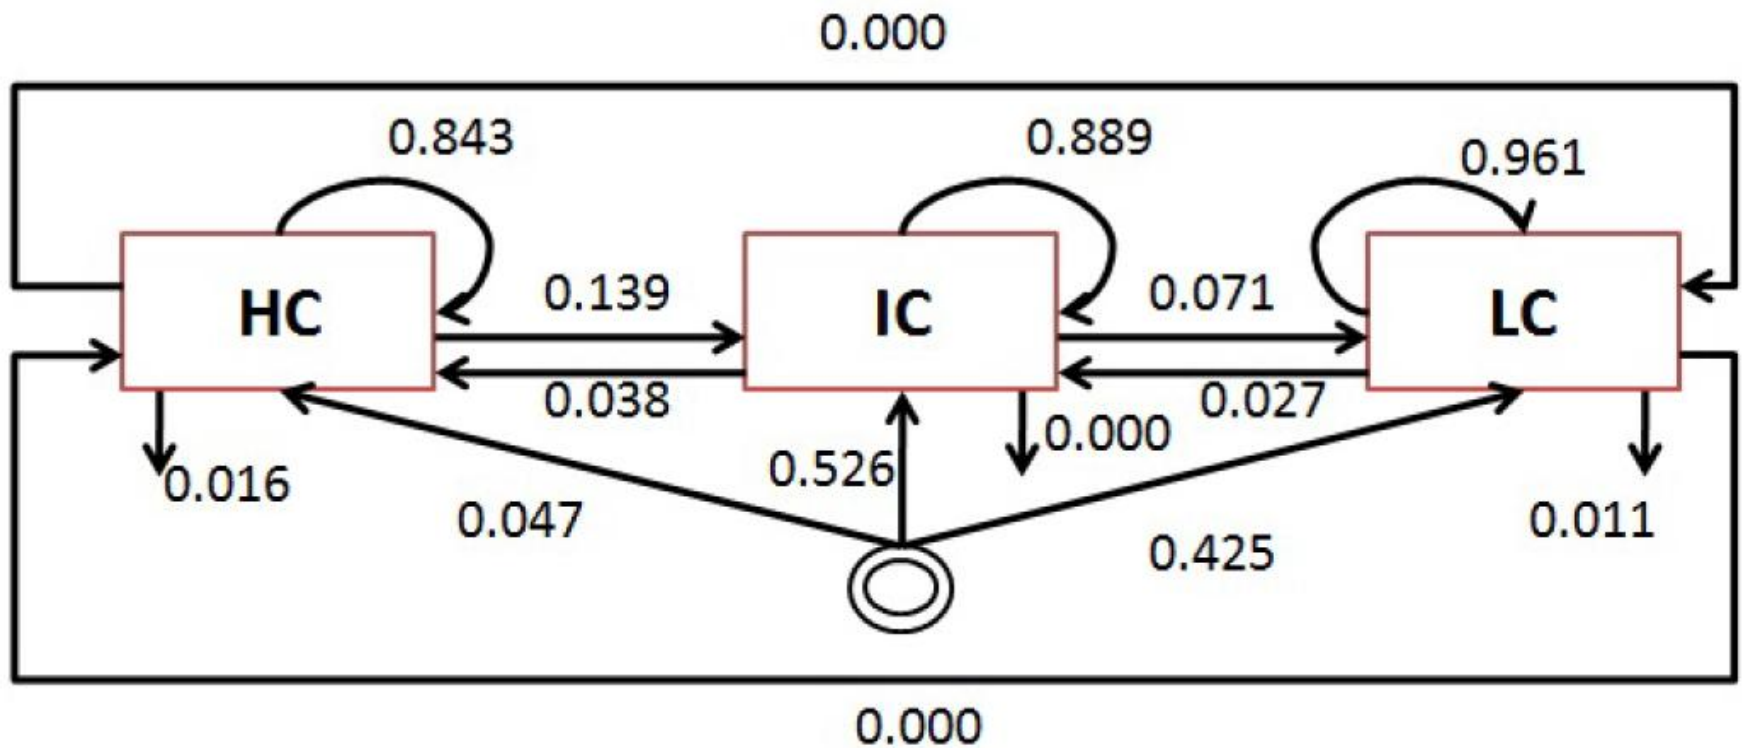

# Changes in The Profile of a Node Over Time

Does a node tend to change its profile very often over a transmission?

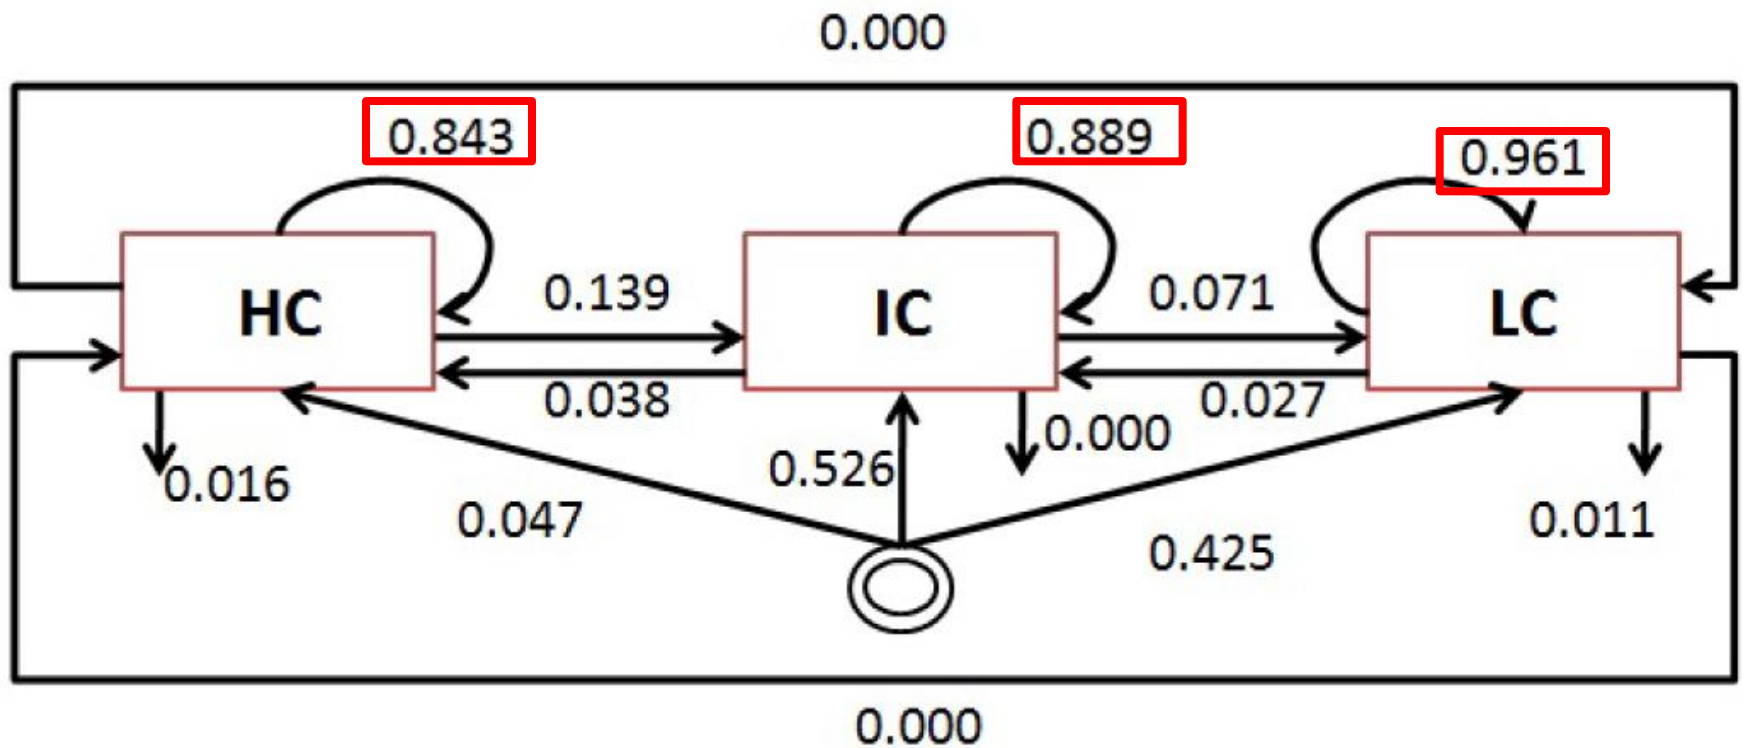

- Customer Behavior Model Graph (CBMG)
  - State transition model
  - States: centrality profiles
  - Transition: labeled with probability of a node changing between two profiles
- Represents the dynamics of the nodes

# Changes in The Profile of a Node Over Time

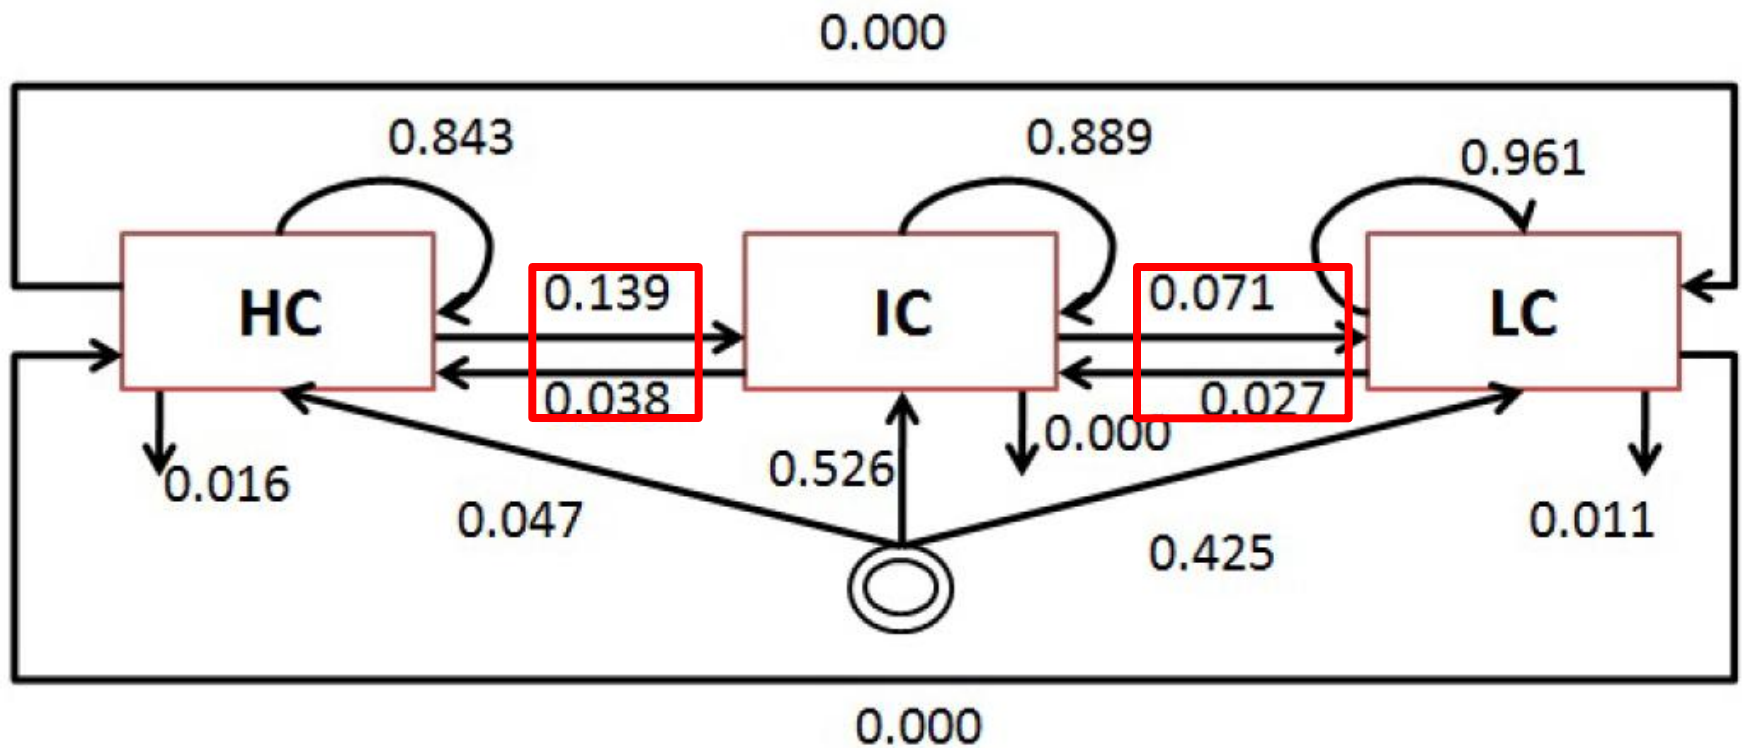

Changes between centrality profiles  
for a given node

# Changes in The Profile of a Node Over Time

High probability of a node remaining with the same profile over a transmission

# Changes in The Profile of a Node Over Time

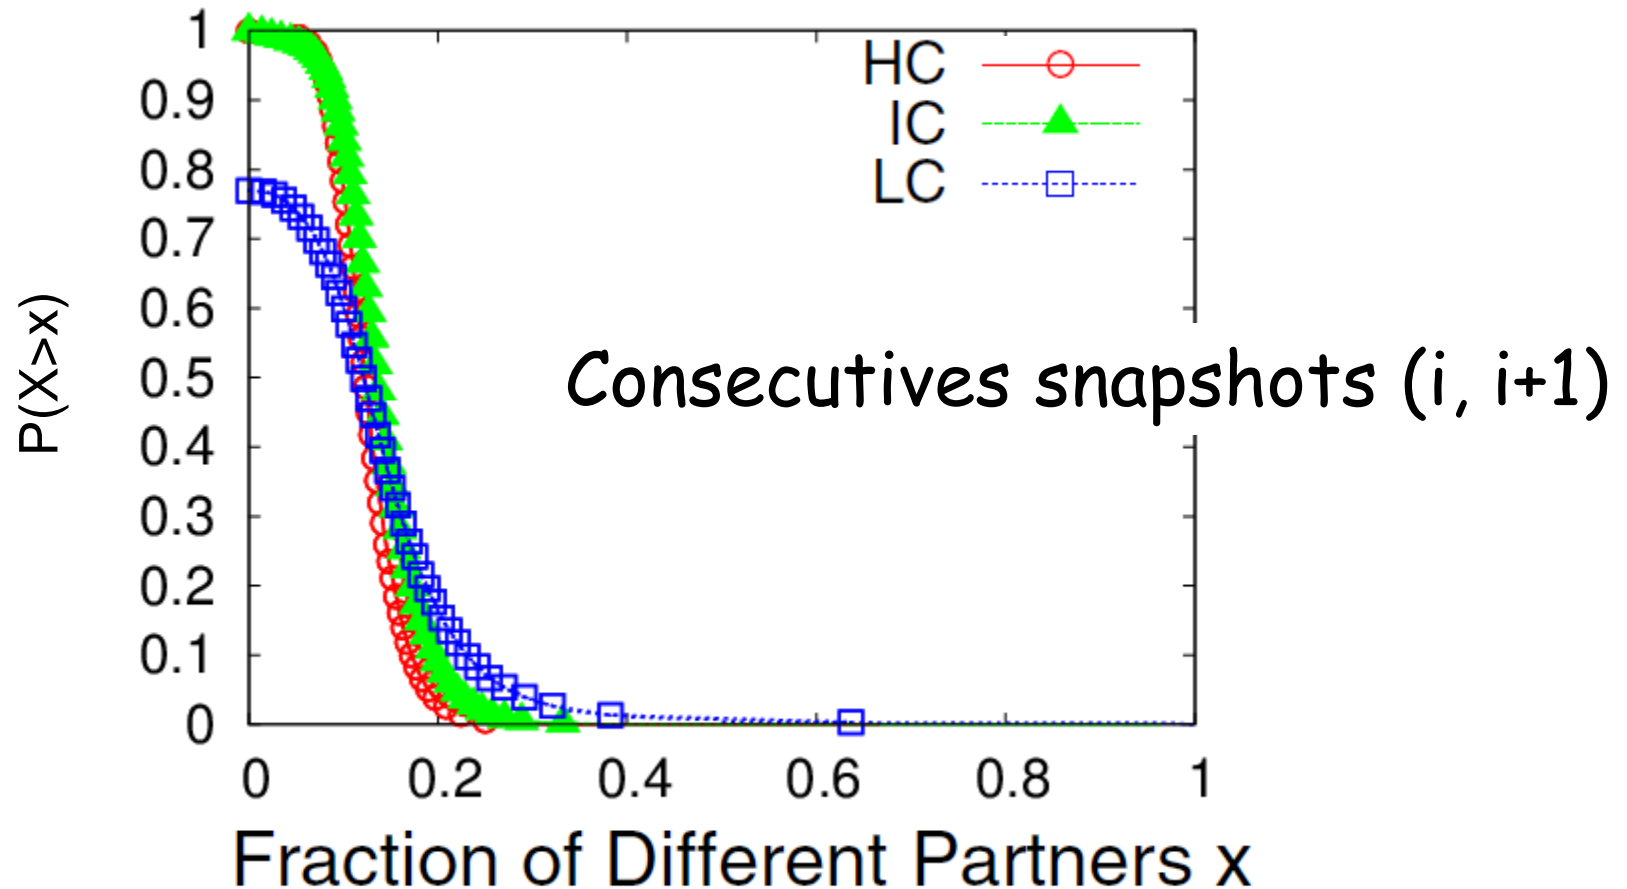

Higher probability of a node centrality to decrease than to increase

# Main Steps

- Properties of individual nodes
  - ✓ Centrality profiles
  - ✓ Changes in the profile of a node over time
  - Changes in the list of partners over time
- Properties of network as a whole

# Change The Nodes Partnerships

- Nodes have up to  $\approx 30\%$  different partners

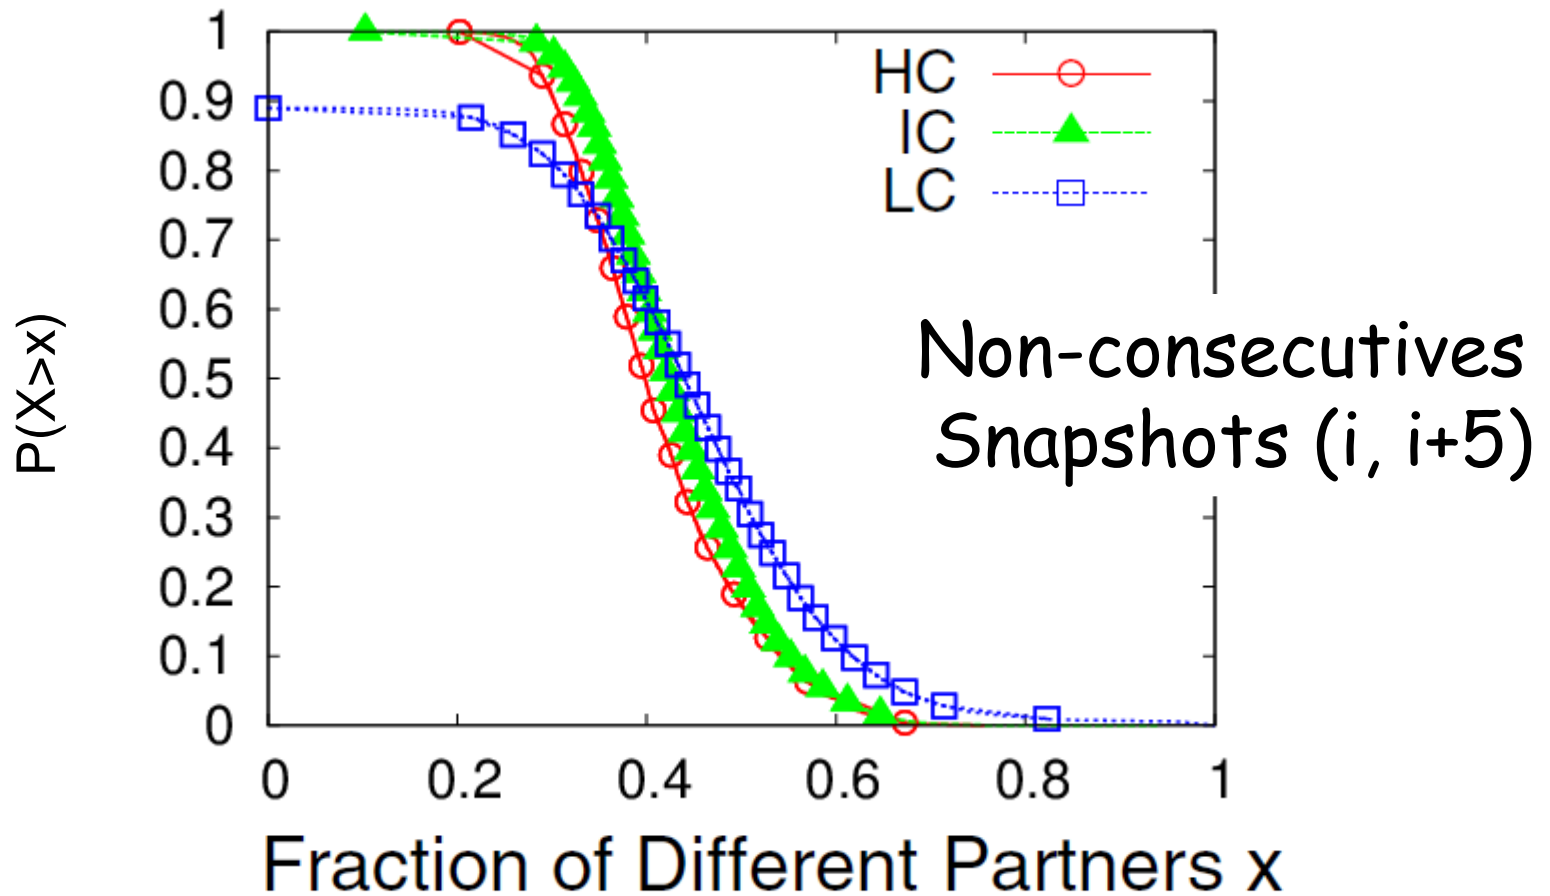

# Change The Nodes Partnerships

- Nodes have up to  $\approx 50\%$  different partners

# Change The Nodes Partnerships

- Nodes have up to  $\approx 70\%$  different partners

# Main Steps

- ✓ Properties of individual nodes
  - ✓ Centrality profiles
  - ✓ Changes in the profile of a node over time
  - ✓ Changes in the list of partners over time
- Properties of network as a whole

# Network Properties Over a Transmission

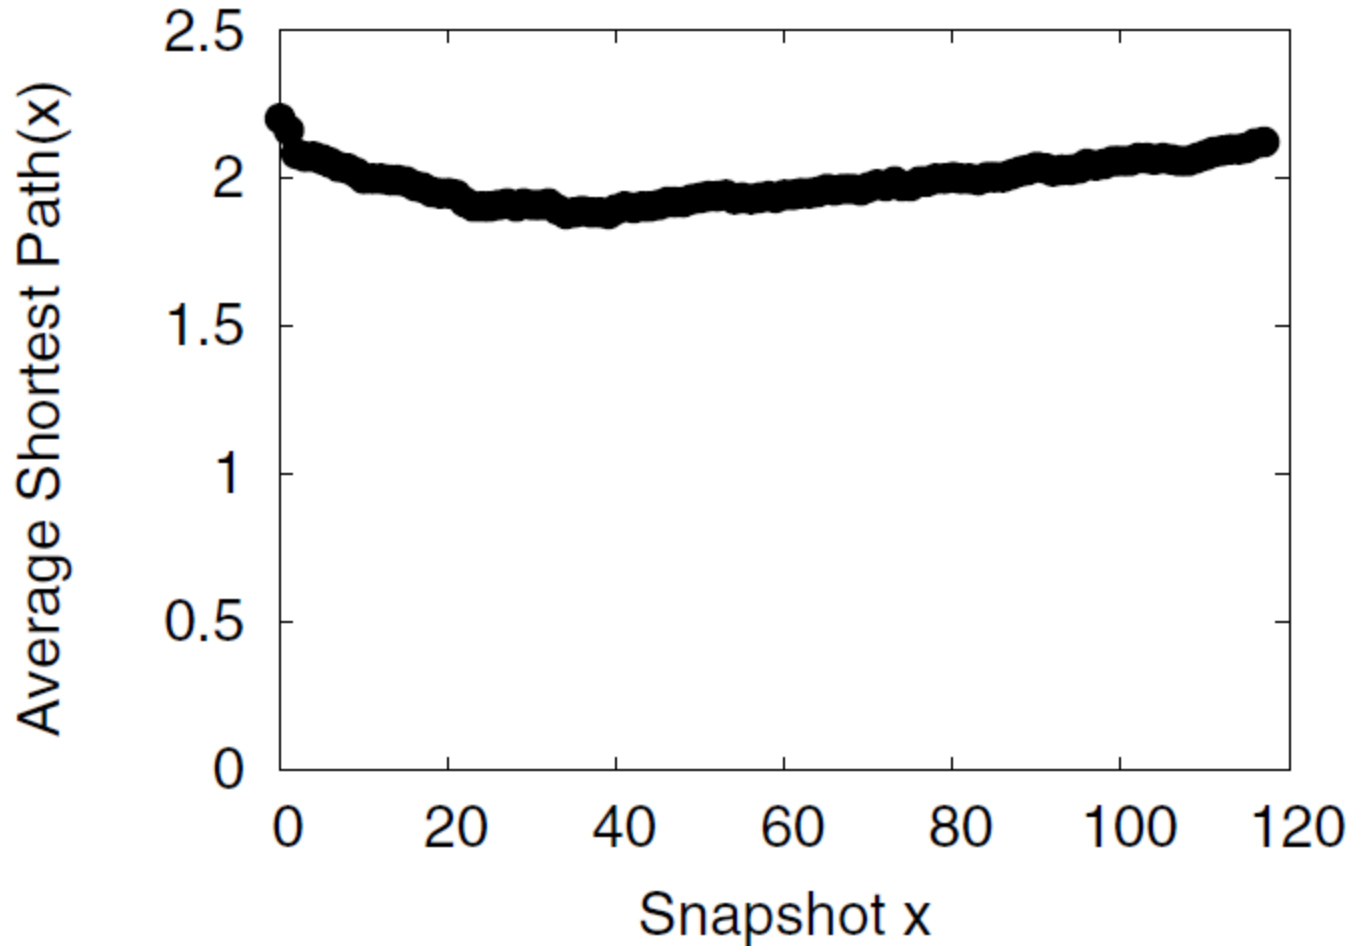

- Diameter (network dispersion)
  - Maximum distance between any two nodes
- Average Shortest Path
  - Shortest path of a node for all other nodes using breadth-first search
- Clustering Coefficient
  - Average node clustering coefficient
  - Node Clustering Coefficient: probability to have an edge between two of its neighbors
- Maximum Degree: the largest degree of any node

# Diameter

It tends to remain stable between 4 and 5

# Average Shortest Path

It tends to remain stable  $\approx 2$

# Clustering Coefficient

It decreases due to new partnerships  
between nodes over time

# Maximum Degree

It remains stable between 300 and 400 partnerships

# Conclusions and Future Work

- Conclusions
  - Three centrality profiles
  - Over a transmission:
    - Nodes tend to remain with the same centrality profile, despite the change in partnerships
    - Network tends to remain stable (exception: clustering coefficient)
  - In general: little dynamism
- Future Work
  - Validate findings in other applications (PPLive)
  - Build realistic P2P live streaming simulation environments

# Thanks!
